Agent Reliability Audit: Pitch for Companies

Oct 13, 2026 · @Omkarr

The problem

AI agents fail quietly: they look fine in a demo and still pick the wrong tool, call tools they didn't need, loop, or break your business rules in production.

These are three separate problems, and most teams can't see any of them today:

- **Wrong tool:** the user asks to book an appointment and the agent looks up pet details instead.
- **Wasted calls:** the agent calls tools it didn't need, which adds cost and delay.
- **Wrong order or broken rules:** the agent books before confirming ownership, or repeats the same call three times.

What we do

We test how your agent behaves, not how it was built: we watch what it does, score it, and show you where it breaks. This is black-box evaluation, the way a QA team tests software it didn't write.

Every agent is scored on the same checks:

- **Tool selection:** did it pick the right tool?
- **Arguments:** did it pass the right details?
- **Tool necessity:** did it need a tool at all?
- **Sequence:** were tools called in a sensible order?
- **Loops and efficiency:** did it repeat or over-call?
- **Your business rules:** did it respect the rules you care about?

Only three things are specific to you: your tool list, a set of example questions with the expected tool, and your rules. The scoring engine itself is the same for every client.

What we need from you

We don't need your source code. We need three things, and the access level is your choice.

1. **Your tool list:** names and one-line descriptions of what the agent can call. You can paste it in an email.

2. **A way to observe the agent**, using one of the options below.
3. **Your business rules,** in plain English, from a 30-minute call.

Access option	What you give us	What changes on your side
A. Test endpoint	An API or chat URL we send test questions to	Nothing in your code
B. Trace export	Redacted logs of past agent runs	Nothing in your code
C. Self-install tracing	Our short setup guide; your engineer adds recording	About 2 small code additions, done by your team on our guidance, or our team.
D. Code access	Repo access under NDA	Only if you want us to do the setup for you

What changes in your system

If you pick option C, the only change is a small recording layer, and your agent's behavior stays identical. On VetMedd, our own prototype, it came to one new file, two small additions to one existing file, and two added packages. The agent logic, prompts, tools, model and frontend were not touched.

Part	Change
New recording file	Turns on tracing and sends each chat's steps (question, model steps, tool calls, answer) to Phoenix
Existing chat file	Two small additions so each chat is recorded
Dependencies	Two recording packages added
Agent logic, prompts, tools, model, frontend	No change

Two safety properties come with it:

- **Fails safe:** if the recording service is off, the chat still works and simply isn't recorded.
- **Fully reversible:** delete the new file, revert the two edits and the package change, and you are back to before.

What you receive

You get a live view of your agent's behavior plus a written audit with specific fixes.

- **Dashboard (read-only):** chats, tool calls, errors, average and slowest response times, a chart of which tools are used, and any single chat opened step by step. Chats with no tool use and chats that repeat one tool 3+ times are highlighted.
- **Scored report:** results for tool selection, arguments, necessity, sequence, loops and your business rules, for example "1,000 tool calls: 742 needed, 183 wasted, 75 questionable."
- **Failing examples:** the exact conversations behind every score, so your team can reproduce each problem.
- **Fix recommendations:** clearer tool descriptions, prompt changes and guardrails, ranked by impact.
- **Plain-language guide:** a short explainer so non-engineers can read the results.

How the engagement works

A first audit is a short, fixed-scope pilot (proposed timing, adjustable):

1. **Kickoff call:** we collect your tool list and business rules, and agree on an access option.
2. **Setup:** we connect to your agent through your chosen option.
3. **Test set:** we draft 50–100 example questions with expected tools; you review them.
4. **Run and score:** we run the checks and review a sample of results by hand before sharing any number.
5. **Readout:** we walk your team through the report and the fixes.
6. **Optional ongoing monitoring:** monthly re-runs to catch regressions.

Data privacy. Evaluation can run on redacted or locally stored data, and the dashboard only reads data and never changes it. We will sign an NDA, agree what is stored and where, and delete data when the engagement ends.

Proof: VetMedd, our first worked example

VetMedd is a prototype vet-care chatbot with pet and doctor agents, and we ran this exact setup on it first. Every chat is now recorded, and a read-only dashboard shows chats, tool calls, errors, speed and tool usage, with step-by-step views of single chats. The chatbot's answers and behavior are unchanged.

We will add real audit scores from VetMedd (tool accuracy, wasted calls, loops) here once the first evaluation run is complete.
